

SyncHarbor

Reviewable REST Data Synchronization

Independent software project | Owner: Ismail Habib | Created September 2026

Actual application capture. Any example records are labeled verification inputs.

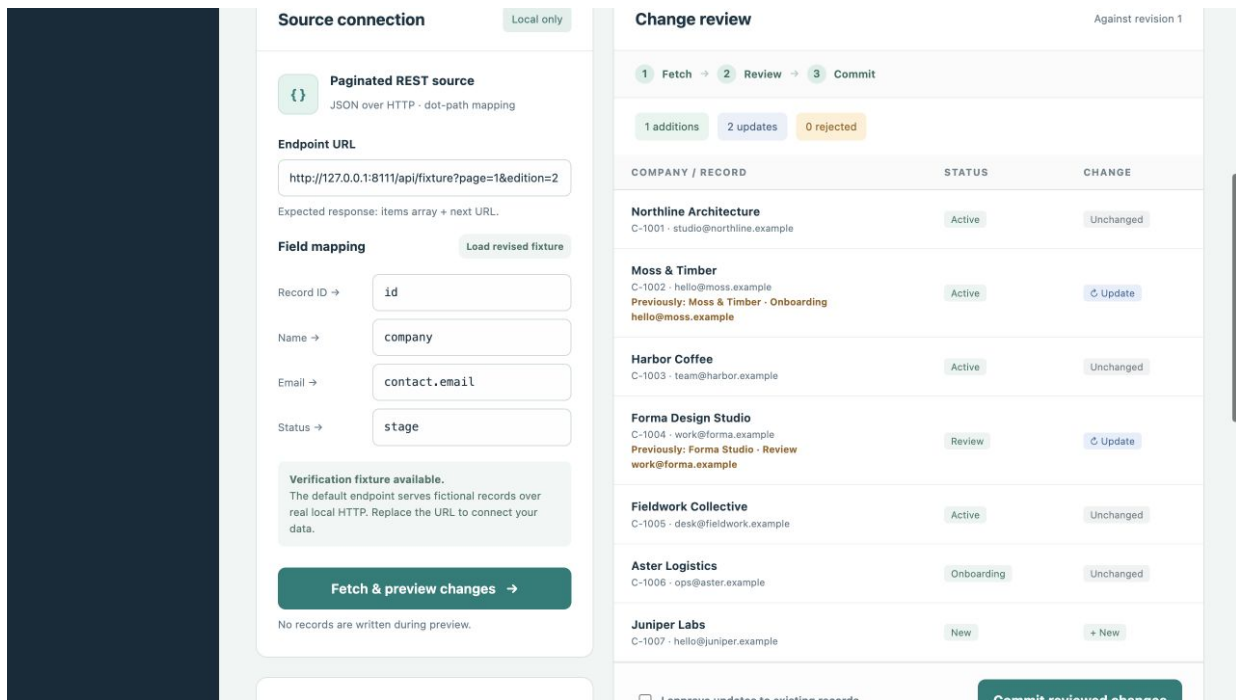

The problem

Manual data transfers make changes hard to inspect and recover from when paginated API records differ from the saved dataset.

What the project delivers

- Real paginated HTTP fetches with field mapping
- Add/change/conflict review and optimistic revision checks
- Atomic SQLite commits and recovery snapshots
- CSV/JSON export with spreadsheet-safe CSV values

Built to be inspected.

A revised source produces one addition and two modifications against saved records, ready for explicit review before commit.

What was verified

9 automated tests passed, including actual loopback HTTP pagination, approved updates, stale-preview rejection, exports and reversible restores.

How it works

HTTP JSON source to Pagination & mapping to Addition/change review to Explicit commit to SQLite snapshot to CSV/JSON export

Current scope

New independent project; fictional verification data. Single-user local service; documented items/next JSON envelope. Remote endpoints require explicit opt-in; OAuth, scheduled sync and public deployment are not implemented.

Included: source code, setup guide, tests, screenshots, editable case study and Malt copy.
